Simulating single-shot images of ultracold atoms

Axel Lode

Host: Misha Lemeshko

Ultracold atoms are usually imaged in experiments in single-shot images. These images are a projective measurement of the many-body wavefunction. Such single-shot images thus correspond to drawing a random sample from the probability distribution associated with the wavefunction. This talk will discuss single-shot simulations performed with the MCTDH-X software [0], their effect on the interpretation of computations with MCTDH-X and experimental observations, and give some prospects on how to better extract and understand their information content. MCTDH-X-based single-shot simulations recently helped to characterize the experimentally observed granulation of a Bose-Einstein condensate (BEC) [1] and to identify the fragmentation of a BEC in a cavity [2] as well as a measurement protocol for the crystal state of ultracold dipolar bosons [3].
