

Seminar/Talk

Empirical Bayes estimators for Poisson and normal means

Yuri Polyanskiy

Massachusetts Institute of Technology

Host: Marco Mondelli

Consider the following classical (unsupervised learning) problem of estimating the mean of an n -dimensional normally (with identity covariance matrix) or Poisson distributed vector under the squared loss. The framework of empirical Bayes (EB), put forth by Robbins'1956, combines Bayesian and frequentist mindsets by postulating that the mean's coordinates are sampled iid from an unknown prior and aims to use a fully data-driven estimator to compete with the Bayesian oracle that knows the true prior. The figure of merit is the total excess risk (regret) over the Bayes risk in the worst case (over the class of, e.g., priors with a given support). Although this paradigm was introduced more than 60 years ago, little was known about the asymptotic scaling of the optimal regret before our work established it to be $\Theta((\log n / \log \log n)^2)$ for the Poisson case. The same rate is shown to be a lower bound for the normal case, verifying and strengthening upon an old conjecture of $\Omega(1)$ due to Singh'1979. We will discuss practical implementation of EB estimators. The most performant of those are obtained by first running a non-parametric maximum likelihood (NPMLE) to estimate the unknown prior, and then computing (via Bayes) the posterior mean with respect to the estimated prior. We will discuss empirical results on sports data and short-term time series forecasting. Based on joint works with Yihong Wu, Soham Jana and Anzo Teh.

Thursday, May 5, 2022 04:00pm - 06:00pm

Meeting ID: 695 6155 8364 Passcode: 497872

This invitation is valid as a ticket for the ISTA Shuttle from and to Heiligenstadt Station.

Please find a schedule of the ISTA Shuttle on our webpage:

<https://ista.ac.at/en/campus/how-to-get-here/> The ISTA Shuttle bus is marked ISTA Shuttle (#142) and has the Institute Logo printed on the side.
